Prague, Casopis Lekaru Ceskych, Vol CII, No 25, 21 June 63, pp 699-700.

Abstract: Described is a test the purpose of which was to eliminate the interference of an increased level of blood lipides in the refractometric test. Serum nitrogen was determined by means of a microchemical method and a gradient cylinder was used to determine proteinemia, both operations being part of a refractometric determination. A table contains comparative data found in normal persons and patients suffering from familiar hypercholesterol xantomatosis. Sixteen references, including 13 Czech.

An experimental study of the electrode spots in condensed spark discharges. On the assumption that the discharge current flows into the luminous area of the spots, local current densities $\sim 10^3$ A/cm² occur. Various techniques are described with which, for example, the spot movements during the discharge may be followed.

 Title : Current Density in Anode Spots of Spark Discharges in Air Under Atmospheric Pressure.

Orig Pub : Geskosl. casop. fys., 1957, 7, No 2, 175-181

Abstract : An investigation of anode spots in spark discharges at atmospheric pressure was made by photographing the anode spots with a high speed photographic camera and by taking oscillographs of the anode current. To obtain current pulses of 500 to 5,000 amp at a duration of 100 to 0,000 microseconds, the discharge of a capacitor through a thyatron was used. The processes in the spot were strongly effected by the surface cleanliness (particularly in the case of anodes made of tin, cadmium, and zinc). In the case of strongly oxidized materials, the spot

Card : 1/2

was broken up into individual parts, which did not change the position during the entire period of glow of the spark. In the case of pure surfaces, the spot could also consist of individual parts, however the erosion trace, left by the spot, was considerably greater. The fixation of the spot, in the case of an oxidized surface, is due to a lower heat conductivity and greater melting temperature of the oxides compared with the pure material. In the presence of oxide, the current density also increases. In the case of commercial carbon, the internal impurities act in analogy with surface oxides. For spectrally pure carbon, the current density was constant during the discharge and equal to the final value for the technical carbon. The measurement data showed that the current density at different anode materials ranges from 2 to 8×10^4 amp/cm². If one assumes uniform distribution of current over the spot, then it is possible to separate several groups of materials, which have constant values of current per atom of surface. current in the individual anodes indicated whether the material of the anode influences the positive column of the glow discharge. The discharge occurred in a pumped-out glass tube 50 mm in diameter, the discharge length being approximately 150 mm. The cathode was an iron cylinder (source voltage 1500 v) or a tungsten wire 0.14 mm in diameter (voltage 40 - 60 v). The discharge current was measured in the interval from 1 to 10 ma in the case of emission from a cylinder or in the interval from 1 to 100 ma in the case of emission from the wire. The investigated anodes were half-round plates, on the active surface of which there was deposited, electrolytically or by some other method, layers of chemically-pure investigated substances. The measurements were made at pressures of 10^{-1} - 10^{-3} mm mercury. The vapors of the anodes were covered with the following

AUTHOR: Šobra, K.

TITLE: Method of determining the structure of material and
of measuring the distance between atoms, and equipment
for utilizing this method
Patent Application Class 42k, 48, PV 444-60 dated
21.1.1960

PERIODICAL: Hutnické listy, no.9, 1962, 671

TEXT: The method is based on determining the distribution
between two anodes of the cathode current of a glow discharge,
whereby one of the anodes is made of the tested material whilst
the other is a known reference material. From the ratio of the
measured currents and the known atomic radius of the reference
material, the atomic radius of the investigated material is
calculated. The subject matter of the invention consists in the
fact that after determining the anode currents, measured at an
equal potential of the anodes, the anode voltages are changed in
such a way that the anode currents equalize. Then, the structure
of the material is determined from the known relation between the
Card 1/2

Method of determining the ...

E073/E535

magnitude of the inter-anode voltage when the currents are equal, and the ratio of the anode currents when the anodes have the same potential. The atomic radius is measured during gradual melting or during gradual solidification of the material which is being investigated. The application contains two schemes (circuit diagrams) of the instruments under consideration.

AUTHOR: ^{44,55} Sobra, K.; ^{44,55} Kalivoda, L'; ^{44,55} Hanitz, F.

TITLE: Contribution to study of splitting of plasma shock waves in accelerating tube

SOURCE: Chekhoslovatskiy fizicheskiy zhurnal, v. 15, no. 7, 1965, 534-535, and insert on p. 540a

TOPIC TAGS: ^{21, 44, 55} plasma shock wave, shock wave structure, ^{21, 44, 55} plasmoid acceleration, plasma magnetic field

ABSTRACT: The authors have observed that when a shock wave is accelerated between straight conductors in a plasma, the plasmoids are emitted with different velocities, thus indicating a splitting of the shock wave. Since this phenomenon is similar to that occurring in a Marshall jet, the authors attempt to attribute it to a similarity in the configuration of the internal magnetic field in both cases. Just as in the Marshall tube the magnetic field at the middle conductor is larger than at the jacket, so is the magnetic field inside straight conductors much larger at the two conductors than in the middle between them. The authors therefore express the opinion that one of the main causes of the splitting of the shock wave

Card 1/2

in a tube of straight conductors and of the plasmoid and the Marshall jet is the great nonuniformity of the internal magnetic field. "This work was carried out at the instigation of Assistant Professor J. Kracik to whom the authors are grateful." Orig. art. has: 2 figures.

ABSTRACT: To increase the output power of a frequency converter using direct-coupled transistors, the following recommendations are made: a) operate the converter with singular input-to-output frequency ratios to assure a uniform transistor loading with average current; b) to reduce switching losses and losses during operation in transistors, a compound transistor circuit should be used in series with a semiconductor diode, and to reduce losses in the second transistor due to deep saturation, a resistor should be used in its collector circuit, and c) use pulsed transistor overloading to preserve their nominal average loading. TO PIC TAGS: frequency converter, thyristor, transistor

ABSTRACT: Controlled frequency converters (CFC) using high-power elements with a key characteristic (transistors or thyristors) are investigated. The CFC circuits in question have no intermediate a. c. to d. c. conversion for further inversion. The power section of the CFC is designed as a reversible bridge circuit (3 single-phase CFC using bridge circuits). The circuit operation is

Card 1/2

O

described. The use of this circuit permits exclusion of short-circuit currents, in the CFC groups and virtually currentless switching between the groups; it is possible therefore to avoid the use of reactors. Switching losses equal about one half as numerous as in CFCs using intermediate conversion (rectification). The absence of reactive elements in the power circuit makes it theoretically possible to obtain an unlimited range of frequency variations. AUTHOR: Tacikowski, U. and Sobusiak, T. (P)

TITLE: Diffusion chrome plating of instrument steel using ferrochrome powders 27

PERIODICAL: Referativnyy zhurnal, Khimiya, no. 5, 1963, 353, abstract 5K37
(Prace Inst. mech. precyzynej, 1962, Vol. 10, no. 35, 32 - 50)

TEXT: The effect of granulation of ferrochrome (~4% C) on the thickness and quality of chrome plated layers was studied. The formation of a quality chrome plate on poor chrome plating steels is possible by a very finely granulated ferrochrome (0.001 - 0.005 mm). In cases of good chrome plating steels an increase in the size of the grains of ferrochrome decreases the thickness of the diffused layer. Among the investigated steels, unalloyed high carbon steels (75, N1E) and alloyed chrome and chrome-tungsten steels (NC4, NC6, MWC) took the chrome plating well. High carbon high chromium steel (NC10) and also low alloyed middle carbon steels (WNL, NZ3) took the chrome plate poorly. The influence of the type and quantity of the activator in the

Card 1/2

L 12286-63

Diffusion chrome plating of

s/081/63/000/005/043/075

powder and the dependence of these factors on the granulation of the ferrochrome was established. The type of activator (NH_4I , NH_4Cl) has no effect when the ferrochrome is fine grained. When the ferrochrome is coarse grained the action of NH_4I has a much better effect on the chrome plating. The increase in the number of activators in powder of fine grained ferrochrome brings about a decrease in the thickness of the coat, but with coarse grains, the coat thickens and its quality is affected. The best results in chrome plating are obtained when a fine grained ferrochrome (0.001 - 0.005 mm) containing 0.5% activator is used. The effect of temperature and time of process on the chrome plating, and also means of regenerating the processed powder of ferrochrome is also described. The article contains a 7 item bibliography. ✓ 5320. A NEW DOUBLE INDUCTION REGULATOR. ²J. Socht.
Elektrotech. Obzor, Vol. 48, No. 5, 235-41 (1957). In Czech.
Conventional and special designs of induction regulators are described in order to compare these with the new design. It consists of three wound-core annular armatures separated by two axial air-gaps. The top and bottom armatures are mounted on a common shaft, and provided with three-phase windings in radial slots on the bottom face of the top armature and on the top face of the bottom armature. The common secondary between the two primaries is rigidly mounted in the frame and carries windings in radial slots on both faces. A four-parallel-branch secondary winding with negligible equalizing currents is discussed. The outer diameter of this machine is about 30% larger than that of a conventional machine but the total height and the copper weight are reduced by half. The manufacturing difficulties of the design are pointed out.

✓ Regeneration of electrolyte used in electrolytic polishing of carbon steel. I. Oxidation of chromium. Tadeusz Zak and Ja. Socha (Inst. Met. Aparatury Nauk-Lab. Warsaw) *Prace Inst. Mech.* 4, No. 12, 11-15(1954)(English summary).—Regeneration of spent soln. contg. H₂SO₄, H₃PO₄, and some Cr(III) and Cr(VI) was done by anodic oxidation (I) of Cr(III) to Cr(VI). Pilot-plant investigations were performed on 20 l. of a water soln. contg. H₂SO₄ 12.5, H₃PO₄ 65%, and Cr₂O₃ 1350 g., out of which 600 g. was reduced cathodically to Cr(III) (in order to imitate spent conditions). I was carried out at 100° with a c.d. of 9 on the Pb anode and 200 amp./sq. dm. on the Pb cathode. The surface of the anode was 8 sq. dm. The cathode was surrounded by a ceramic diaphragm. Under these operating conditions H₃PO₄ inhibition of I of Cr was the smallest. When Cu ions were present the cathodic c.d. had to be smaller because Cu lowered the cathodic potential. Elec. co-

lytic polishing of C steel could be carried out with solns. in which Cr(III) content was allowed to build up to a max. of 2%. The spent solns. could then be regenerated until Cr(III) content dropped to approx. 0.5%. During regeneration, which lasted many hrs., the surface of the anode became coated with a fine brown sediment while a small amt. of PbSO₄ settled to the bottom of the diaphragm. It was thought that PbO₂ was the carrier of electrons during I of Cr: $Pb - 4e^- = Pb^{4+}$ and $3Pb^{4+} + 2Cr^{+++} + 7H_2O = 3Pb^{++} + Cr_2O_7^{--} + 14H^+$. Another possible mechanism of I was as follows: $2SO_4^{--} - 2e^- = S_2O_8^{--}$ and $2Cr^{+++} + 3S_2O_8^{--} + 7H_2O = Cr_2O_7^{--} + 6SO_4^{--} + 14H^+$.

Socha J. Electrolytic Chrome Plating in a Selfsteering Bath.

"Chromowanie elektrolityczne w kąpielach samostierujących". Przegląd Mechaniczny, No. 6, 1956, pp. 276-283, No. 9, 1956, pp. 327-329, 13 figs., 2 tabs.

2
A description of the composition of the selfsteering bath and the conditions under which the chrome plating process develops, the dependence of current output on current density and temperature being shown graphically. Among the problems discussed are the working zone of the bath, the characteristics and metallography of chrome plating, such defects in chrome plating as appear when instructions for this process are not strictly followed, the causes of defects and the methods of eliminating them. The advantages of selfsteering baths as compared with the more conventional techniques are: increase in output by current of about 50%; greatly increased working zone; improved resistance properties of the coated parts; improved coating capacity; greatly facilitated additional chrome plating; highly simplified maintenance of baths, and reduced hydrogen liberation which improves the degree of safety in working conditions.

Title : An Investigation of the Possibility of Perfecting the
Process of Electrolytic Chrome Plating. Ch. II.

Orig Pub : Prace Inst. mech., 1957 (1958), 7, No 22, 41-44.

Abstract : By a method described earlier (RZhKhim, 1957, 64027)
the operation of a self-regulating bath (SB) for chrome
plating, which contains 400 g/l of CrO₃ (I), was studied.
An increase of the concentration of I permits obtaining
good protective-decorative coverings at lower temperatu-
re and D. The SB plating method is equivalent to the
usual bath plating method at an I concentration of 275
g/l; at a higher concentration of I, SB works better.

TITLE: Bright ²¹gold ¹⁰plating in an acid electrolyte

SOURCE: Warsaw. Instytut Mechaniki Precyzyjnej. Prace, v. 13, no. 2(48), 1965, 1-8

TOPIC TAGS: nickel, cobalt, metal plating, electrolyte, ~~gold plating~~, GOLD

ABSTRACT: The effect of citric acid, nickel, and cobalt ions on the formation of bright coatings has been investigated. The investigation was based on a hypothesis of the existence of two kinds of brighteners. The polarization, current efficiency, and brightness of coatings in various concentrations of citric acid, nickel, and cobalt salts made it possible to select optimum conditions for bright gold plating. The Effect of Technological Processes on the Mechanical Properties of ZnAl 41 Strips (Zn-Al-Cu). S. Socha (*Prace Inst. Min. Hutn.*, 1934, 6, (2), 74-82). ~~See also~~ The casting of ZnAl 41 alloy (Zn ~95, Al 4, and Cu 1%) by continuous and semi-continuous methods is described. Castings of best technological properties were obtained by the semi-continuous method at casting temp. of 405° C., using shallow ingot moulds with removable bottoms and radial cooling. Subsequent hot rolling of 9-mm.-thick strips at 230°-250° C. down to 4-5 mm. thickness, followed by finish-rolling to 1.2 mm. at 80° C. produced strips with 35% elongation. Hardness and resistance to alternating bending stresses was found to increase with the annealing temp. in the range 100°-300° C., with the elongation decreasing and the U.T.S. remaining almost const.—S. *Surface Flaws in Zinc Coatings on Steel Sheets. S. Socha and W. Sullis, *Proc Inst Minist. Metall.*, 1954, 6, (5), 247-250. — [In Polish]. Defects occurring in Zn coatings on mild steel rolled in batches or by the Sendzimir method are reviewed. The causes of such flaws were investigated by analysing the effect of prior rolling defects and mill scale. Sheets with various rolling defects were pickled for various times before hot dipping. Increase in the length of pickling time and frequent washing reduced subsequent defects in coatings; overpickling reduced such defects still further, but at the expense of a loss of brightness of the coating. A series of tests were carried out on the reduction of mill scale by molten Zn, using compacts of synthetic Fe_2O_3 immersed in Zn at 450° C. for varying times. Metallographic examination showed large crystals of Fe-Zn in a background of Zn and some un-reduced Fe_2O_3 . The amount of un-reduced Fe_2O_3 increased with increasing sintering temp. of the compacts. Similar experiments on a 0.12% C steel annealed in air at different temp. showed that the scale produced at higher temp. was less susceptible to reduction by Zn. The defects observed were classified according to their appearance as droplet formation or rivulet formation. The former is attributed to local surface concentrations of cementite, leading to decreased adhesion of Zn; the latter to the reduction of scale trapped in surface flaws. This scale, not removed by pickling, leads to the formation of Fe-Zn compounds which locally increase the viscosity of the Zn, and causes uneven flow over the surface.—W. E.

Soc HA, S.

Zinc alloy strips Zn-Cu and Zn-Al-Cu from rectified zinc NO and electrolytic zinc EO. S. Socha and I. Zwendling. *Prace Inst. Ministerstva Hut.* 7, 283-91 (1955) (English summary).—The two kinds of Zn investigated here, called zinc NO (I) and zinc EO (II), were both very pure, with only traces of Pb, Fe, Cd, Cu, Sb, Sn, and no As. I was a rectified Zn, whereas II was an electrolytically refined one. Both I and II were used to prep. Zn-Cu alloys; ingots and strips were prepd. from such alloys, and the mech. and tech. properties thereof were tested, such as elongation, hardness, drawability, and effects of annealing. In all these alloys it did not make any difference if I or II was used in the prepn. But the corrosion resistance depended greatly upon the kind of Zn used. I imparted a much better corrosion resistance than II, because the traces of metals present in II added up *in toto* to roughly 3 times the impurities present in I. Werner Jacobsen
